

In Access 2007 I want to:

1. create VBA code to find all .xml files in a specified folder
2. import the content to a table
3. check if the record exists (based on the value of a specified field) in a SharePoint 2007 linked list (as a table)
  - a. if exists, update existing record in SharePoint list with the content of the various fields
  - b. If not exists, append the record to the SharePoint list (various fields)
4. Move the imported xml file to a sub-folder
5. repeat the process until all .xml files have been processed
6. automate this process to run at regular intervals (without human intervention)
